$script_1$

Chapter 1

R as a calculator

R can be used as a calculator. For example, to calculate the square root of the absolute difference between 3^2 and 4^2 , you can use the following code:

```
3^2
exp(2)
log(10)
log10(10)
sqrt(abs(3^2-4^2))
```

Objects in R

You can assign values to objects in R using \leftarrow or = and calculate with them like with numbers. For example:

```
test <- 56
test2 <- 124251762

test + test2
test * test2
```

Objects in workspace can be listed with ls() and removed with rm(). For example:

```
ls()
rm(test)
```

Exercise

Solutions to exercises are as follows

```
3^2
sqrt(9)
pi^2
sqrt(abs(3^2-4^2))

test <- 3^2
test2 <- 4^2
test3 <- abs(test - test2)
sqrt(test3)

log(exp(4))
log(exp(4), base = exp(1))
log(100, base = 10)

factorial(8)
exp(factorial(3))</pre>
```

Chapter 2

Functions in R

Functions are called by passing arguments to them. For example:

```
mean(5)
mean(x = 5)
mean(y = 5)
mean(x="test")
mean(x = test)
```

Functions can also be defined by the user using the function keyword. For example:

```
foo <- function(x, y){
   x^2+y^2
}
foo(y=3, x=5)</pre>
```

Note that functions should only use the arguments that are defined in the arguments section. Avoid using global variables in functions like this

```
foo <- function(x, y){
   x^2+y^2+ test
}
foo(y=3, x=5)</pre>
```

Exercises

1. Formulate the EOQ formula in R

```
cost_eoq_fun <- function(q, d, co, cl) {</pre>
  # returns total cost per period
  # d...demand
  # q...lot size
  # co...ordering cost
  # cl...stock holding cost
  ((1/2)*cl*q)+((d/q)*co)
}
# test cost function
cost_eoq_fun(d=100, q=20, cl = .1, co = 50)
## [1] 251
eoq_fun <- function(co, d, cl) {</pre>
  # return optimal lot size
  # d...demand
  # co...ordering cost
  # cl...stock holding cost
  sqrt((2*co*d)/cl)
}
# optimal lot size
q.star \leftarrow eoq_fun(d = 100, cl = .1, co = 50)
# optimal cost
cost_eoq_fun(d=100, q=q.star, cl = .1, co = 50)
## [1] 31.62278
```

2. Derive a function for calculating weighted Euclidean distance between two points.

```
weuc_d2_func <- function(x,y,w) {
    # calculates weighted Euclidean distance between x and y
    # y,x...vectors
    # w.. weight vector
    sqrt(sum(w*(x-y)^2))
}
# test distance function
weuc_d2_func(x = c(1,2,3), y= c(3,2,1), w=c(1,1,1))
## [1] 2.828427
# result should be sqrt(8)</pre>
```

Alternatively use intermediate variables within the function

```
weuc_d2_func <- function(x,y,w) {
    # calculates weighted Euclidean distance between x and y
    # y,x...vectors
    # w.. weight vector
    tmp.diff <- (x-y)
    tmp.diff.sq <- tmp.diff^2
    tmp.result <- w*sqrt(tmp.diff.sq)
    return(tmp.result)
}
# test distance function
weuc_d2_func(x = c(1,2,3), y= c(3,2,1), w=c(1,1,1))
## [1] 2 0 2
# result should be sqrt(8)</pre>
```

3. Formulate a function for the Geometric Poisson density distribution.

```
geom_pois_dens_fun <- function(n, lambda, theta){
    # calculates density value of geometric Poisson distribution
    # n...integer, demand/successes, theta,lambda..parameters
    k.vec <- 1:n
    sum(exp(-lambda)*lambda^k.vec/factorial(k.vec)*(1-theta)^(n-k.vec)*choose(n-1, k.vec-1))
}
# test function
geom_pois_dens_fun(n=3, lambda=.5, theta = 2)
## [1] 0.1642687</pre>
```

Chapter 3

Basics on data types and data manipulation

Create vectors

There are numerous ways to create vectors in R. For example, you can use the c() function to concatenate elements into a vector:

```
x \leftarrow c(1,2,3,4,5)
# not working as expected because different data types
y \leftarrow c(1,2,3,5, \text{"test"})
y \leftarrow 1:5
rep(x = y, times = 10)
x \leftarrow rep(x = y, each = 10)
z \leftarrow c(y,x)
zz \leftarrow seq(from = 10, to = 35, by = .25)
```

Create matrices

Matrices can be created by combining vectors or using matrix(). For example:

```
# matrix with numbers
A <- matrix(1:9, ncol=3)
# matrix with characters
B <- matrix(letters[1:9], ncol=3)
# matrix by column-binding
C <- cbind(c(1,2,3,4,5), c(6,7,8,9,10))
# for data frames similar
df.1 <- data.frame(zz[1:30], as.character(zz[1:30]))</pre>
```

Indexing vectors and matrices

Vectors and matrices can be indexed using square brackets. For example:

```
x <- 1:10
# first element
x[1]
# first five elements
x[1:5]</pre>
```

```
# last element
x[-1]
# elements greater than 5
x[x>5]

A <- matrix(1:9, ncol=3)
# single element
A[1,2]
# first row
A[1,]
# first column
A[,1]
# first two rows
A[1:2,]</pre>
```

Biathlon data set

The biathlon data set should be imported by "import dataset" menu. Once imported as object biathlon_results_women you can access it as follows:

```
# read data set
library(readr)
biathlon_results_women <- read_csv("data/biathlon_results_women.csv")
View(biathlon_results_women)
# View DataFrame
View(biathlon_results_women)
# overview on race types
table(biathlon_results_women$type)
# overview on competition types
table(biathlon_results_women$competition)
# filter for sprint races only
tmp.id.S <- biathlon_results_women$competition == "S"</pre>
df.sprint <- biathlon_results_women[tmp.id.S, ]</pre>
# mean of total tiem
mean(df.sprint$tot.time)
# filter with tidyverse
library(tidyverse)
```

```
biathlon_results_women %>%
  filter(competition == "S") %>%
  select(tot.time) %>%
  unlist() %>%
  mean()
```

Exercises

1. Calculate the outer product of two vectors (without outer())

```
x < -1:5
y < -10:6
as.matrix(x) %*% t(as.matrix(y))
        [,1] [,2] [,3] [,4] [,5]
                           7
## [1,]
          10
                9
                      8
                                 6
## [2,]
          20
                18
                     16
                          14
                                12
## [3,]
         30
                     24
                          21
                27
                                18
## [4,]
          40
                36
                     32
                          28
                                24
                          35
## [5,]
          50
                45
                     40
                                30
outer(x,y)
##
        [,1] [,2] [,3] [,4] [,5]
                           7
## [1,]
         10
                9
                      8
                                 6
## [2,]
          20
                18
                     16
                          14
                                12
## [3,]
          30
                27
                     24
                          21
                                18
## [4,]
          40
                36
                     32
                          28
                                24
## [5,]
                     40
                          35
                                30
```

2. Define a function that calculates the trace of a matrix.

```
trace_func <- function(z){
    # calculates trace of z
    # z...matrix
    sum(diag(z))
}
tmp <- rnorm(9)
A <- matrix(tmp, ncol=3, byrow = T)
trace_func(A)
## [1] 1.323593</pre>
```

3. Create a vector containing the first 100 Fibonacci numbers. Most commonly, the Fibonacci numbers are defined recursively by $F_n = F_{n-1} + F_{n-2}$ whereby $F_0 = 0$ and

 $F_1=1.$ However, there is also an explicit formulation: $F_n=\sum_{k=0}^{\lfloor \frac{n-1}{2}\rfloor} \binom{n-k-1}{k}$ (check here)

```
fib_num_fun <- function(n){</pre>
  # calculate nth Fibonacci number
  # n...number
  k.vec \leftarrow 0:floor((n-1)/2)
  sum(choose(n-k.vec-1, k.vec))
# vectorize fib_num_fun such that it accepts input vectors
vfib_num_fun <- Vectorize(fib_num_fun)</pre>
# doesn't work
fib num fun(1:10)
## Warning in 0:floor((n-1)/2): numerical expression has 10 elements: only the
## first used
## [1] 10
# works
vfib_num_fun(1:100)

```

4. Create a matrix containing the all binominal coefficients up to n = 50

```
pas <- outer(1:10, 1:10, choose)
```

5. Create a list containing – vector of 5 small letters – vector of 5 capital letters – vector of 5 random numbers

```
11 <- list(small = letters[1:5], capital = LETTERS[1:5], random = rnorm(5))</pre>
```

6. Create a matrix with dimension 4×4 and fill it with random numbers.

```
# set random seed
set.seed(123)
A <- matrix(rnorm(16), ncol=4)</pre>
```

7. For the matrix generated in task 6, check whether its invertable.

```
det(A) != 0
## [1] TRUE
```

8. For the matrix generated in task 6, check whether it is symmetric.

```
A == t(A)
## [,1] [,2] [,3] [,4]
## [1,] TRUE FALSE FALSE
## [2,] FALSE TRUE FALSE FALSE
## [3,] FALSE FALSE TRUE FALSE
## [4,] FALSE FALSE TRUE
```
